Is Tanaka-Johnston mixed dentition analysis an applicable method for a Saudi population?

Moshabab A. Asiry, BDS, MSc, Sahar F. Albarakati, BDS, MSc, Nasr S. Al-Maflehi, BSc (Statistics), MSc (Statistics), Alaa A. Sunqurah, BDS, Monirah I. Almohrij, BDS.

ABSTRACT

الأهداف: اختبار امكانية استخدام طريقة تاناكا وجونسون في المجتمع السعودي.

الطريقة: أجريت هذه الدراسة في الرياض – المملكة العربية السعودية من سبتمبر 2013م إلى يناير 2014م على 409 عينات من نماذج المعالجات التقويمية الجبسية، وقد قام بالقياس عينات النماذج الموسيكية، والを行いاب الضخمة والأسنان السفلية للمضاعف، وتم قياس عرض الأسنان السفلية وال العلياء باستخدام مقياس رقمي رقمي كالتقييم. وقد تم مقارنة نتائج العرض الحقيقي مع النتائج المتوقعة من معادلة قياس تاناكا وجونسون.

النتائج: لوحظ اختلاف النتائج بين الزوايا والمضاعف للعوامل الجنسية في كلا الاشارتين وللخلاف الاحصائي (t-test) (p<0.001). كما لوحظ الاختلاف بين عرض الأسنان السفلية وال العلياء للنماذج الموسيكية ولناء والمضاعف، وتمت مقاربة النتائج من معادلة تاناكا وجونسون. وبناءً على ذلك، تم استخدام تحليل الانحدار لتحديد العوامل القائمة على العرض الحقيقي للعوامل. وبناءً على ذلك، تم الاعتماد على شكل المعادلة التنبؤ يكون مناسبًا للأطفال السعودية (نساء ورجال).

الخاتمة: لوحظ عند دراسة معالجة التقييم للعوامل السفلية للنماذج الموسيكية، استخدم طريقة تاناكا وجونسون لاستخدام عينة معروفة، وتم استخدام عينة معروفة، كناء عينة معروفة، لتحديد العوامل. كما تم استخدام عينة معروفة، لتحديد العوامل في المجتمع السعودي.

Objectives: To test the applicability of the Tanaka and Johnston prediction method in a Saudi population.

Methods: College of Dentistry, King Saud University, Riyadh, Saudi Arabia from September 2013 to January 2014, on a sample of 409 pairs of orthodontic study models.

Results: Gender differences were observed in the sum of the mesiodistal width of canines and premolars in both arches as indicated by t-test (p<0.001). The sum of the actual mesiodistal widths of canines and premolars were compared with the predicted widths derived from the Tanaka and Johnston equation and significant differences were found (p<0.001). The regression analysis indicated that the sum of the mesiodistal width of the mandibular permanent incisors is a good predictor for those of unerupted canines and premolars, with the correlation coefficients ranging from 0.51 to 0.61. Accordingly, 2 linear regression equations were developed for tooth width prediction for Saudi males and females.

Conclusion: The Tanaka and Johnston prediction equation overestimated the sum of mesiodistal widths of permanent canines and premolars in Saudis. New regression equations were formulated for the prediction of tooth width in the Saudi population.

Saudi Med J 2014; Vol. 35 (9) 988-992

From the Department of Pediatric Dentistry and Orthodontics (Asiry, Albarakati), and the Department of Periodontics and Community Dentistry (Al-Maflehi), and the College of Dentistry (Sunqurah, Almohrij), King Saud University, Riyadh, Kingdom of Saudi Arabia.

Received 9th March 2014. Accepted 8th July 2014.

Accurate prediction of the mesiodistal widths of unerupted permanent canines and premolars is a valuable diagnostic tool for assessing and managing tooth size/arch length discrepancies during mixed dentition. Determining the space required to accommodate unerupted permanent canines and premolars is helpful in treatment planning for serial extractions, space maintenance, space regaining, eruption guidance or just observation of the patient. \(^1\)

Three methods have been reported for estimation of the mesiodistal widths of unerupted canines and premolars: 1) measurements of unerupted teeth on radiographs; 2) calculations from prediction equations and tables; 3) a combination of both. \(^2\) Tanaka and Johnston developed linear regression equations for the prediction of the mesiodistal width of unerupted canines and premolars among European ancestry. \(^3\) T is method of prediction has achieved widespread clinical acceptance because it is uncomplicated, flexible, relatively accurate and non-invasive. \(^4\) Several studies investigated the applicability of the Tanaka and Johnston prediction method on different population groups. \(^5\) The results of these studies revealed that the Tanaka and Johnston prediction method is not accurate when applied to those populations. \(^6\) Further, gender differences in the sum of the mesiodistal width of canine and premolars has been reported in literature. \(^7\)

Al-Khadra \(^2\) investigated the reliability of the Tanaka and Johnston equations in Saudis. T his study was based on a small sample size (34 patients) and pooled male and female data without considering the genders separately. T herefore, the aim of this study is to test the applicability of the Tanaka and Johnston prediction method in a Saudi population, and to attempt to develop a new prediction formula for Saudis, if necessary.

**Methods.** T he current study was conducted at the College of Dentistry, King Saud University, Riyadh, Saudi Arabia from September 2013 to January 2014. Sample size calculation indicated that at \(\alpha=0.05\) and 1-\(\beta=0.95\) with estimated standard deviation 1.2mm the sample size should be at least 360 patients. T herefore, 409 pairs of study models were selected from orthodontic records of patients (202 males and 207 females; average age of 15.10 ± 0.45 years) seeking orthodontic treatment at different dental clinics. T he study was reviewed and approved by the College of Dentistry Research Center (CDRC), King Saud University.

T e selected sample fulfilled the following criteria: 1) Saudi patients; 2) age range: 13-20 years; 3) good quality of study models (smooth and free from bubbles, voids, fracture or any distortion); 4) no caries or restoration other than Class I caries/restorations; 5) complete eruption of permanent teeth from the right first molar to the left first molar of the maxillary and mandibular arch; 6) minimal crowding and absence of severely rotated tooth; 7) absence of malformed teeth; 8) absence of tooth wear; and 9) no previous orthodontic treatment.

T e current study was conducted at the College of Dentistry, King Saud University, Riyadh, Saudi Arabia from September 2013 to January 2014. Sample size calculation indicated that at \(\alpha=0.05\) and 1-\(\beta=0.95\) with estimated standard deviation 1.2mm the sample size should be at least 360 patients. T herefore, 409 pairs of study models were selected from orthodontic records of patients (202 males and 207 females; average age of 15.10 ± 0.45 years) seeking orthodontic treatment at different dental clinics. T he study was reviewed and approved by the College of Dentistry Research Center (CDRC), King Saud University.

T e paired-sample t-test indicated that no statistical significant difference was observed between the first and the second readings (\(p>0.1\) and standard errors \(≤0.004\)). Pearson’s correlation coefficient exhibited high correlation between the first and the second readings (0.99 or more).

Statistical analysis was conducted using the Statistical Package for Social Sciences, Version 16.0 (SPSS Inc., Chicago, IL, USA). Descriptive statistics were calculated for the sum of the actual width of canines and premolars and mandibular incisors. T e independent sample t-tests were calculated to compare the tooth widths between genders. Paired-sample t-tests were used to compare the difference between the predicted values derived from the Tanaka and Johnston equation and the sum of the actual width of canine and premolars. Tanaka and Johnston regression equations are: \(Y=10.5+0.5X\) for mandibular teeth and \(Y=11.0+0.5X\) for maxillary teeth, where \(Y\) is the sum of the mesiodistal width of canine and premolars in one quadrant, and the \(X\) is the sum of the mesiodistal width of the mandibular incisors.
Applicability of Tanaka-Johnston analysis to Saudis... Asiry et al

From the study data, new regression equations were formulated for the prediction of tooth width in the Saudi population and expressed as $Y = A + BX$. The constants 'A' and 'B' were calculated for female and male subjects separately.

**Results.** Paired t-test was executed to test the difference in the sum of the mesiodistal width of right and left canines and premolars in both arches. No statistical significance was found at a level of significance of 0.05. Therefore, the results of right and left measurements were combined for statistical analysis. Table 1 shows the descriptive statistics for the sum of the mesiodistal width of the mandibular incisors, maxillary canine and premolars, and mandibular canine and premolars among male and female patients. Gender differences were observed in the sum of the mesiodistal width of canine and premolars in both arches as indicated by t-test ($p<0.001$).

Significant differences ($p<0.001$) were found between the sum of the actual mesiodistal widths of canines and premolars and the predicted widths derived from the Tanaka and Johnston equation for male and female patients (Table 2). Tanaka and Johnston equation overestimated the sum of mesiodistal widths of mandibular and maxillary canines and premolars for male and female patients in the sample of the present study.

**New regression equations.** For the mesiodistal width of maxillary and mandibular canines and premolars of

$\sum$ M ax. CPM - the sum of mesiodistal width of the maxillary canine and premolars, $\sum$ M and. CPM - the sum of mesiodistal width of the mandibular canine and premolars, SD - standard deviation, a & b - constants, r - correlation coefficient, $r^2$ - coefficient of determination, SEE - standard error of estimate.
males (Y), there was a significant linear relationship with the mesiodistal width of lower incisors (X), with respective correlation coefficient of determination in maxilla \( r=0.61; r^2=37\% \) and in mandible \( r=0.60; r^2=36\% \). The simple linear regression equations \( Y=10.3+0.49X \) and \( Y=9.7+0.49X \) were the best fitting equations for predicting the maxillary and mandibular canine and premolar width for males (Y) (Table 3). Similarly, the mesiodistal width of maxillary and mandibular canines and premolars of females can be predicted by the linear equations \( Y=11.7+0.37X \) and \( Y=11.3+0.39X \) (Table 3). These linear regression equations were the best fitting model with respective correlation coefficient of determination in maxilla \( r=0.52; r^2=27\% \) and in mandible \( r=0.51; r^2=27\% \).

**Discussion.** The purpose of the study was to test the applicability of the Tanaka and Johnston prediction method in a Saudi population and to attempt to develop a new prediction formula for Saudis if necessary. The age range of the subjects in the present study was between 13 to 20 years of age to minimize the effect of attrition, caries, or tooth loss on mesiodistal width of teeth.\(^9\) One operator made the measurements directly on the study models using an electronic digital caliper. Zilberman et al.\(^10\) found that measurement with digital calipers produced the most accurate and reproducible results.

It has been reported in the literatures that male teeth are generally larger than female teeth.\(^12\)-\(^15\) In the present study, gender differences were observed in the sum of the mesiodistal width of canine and premolars in both arches. Therefore, the data analysis was performed separately for each gender. The results showed that the Tanaka and Johnston equation overestimated the sum of mesiodistal widths of mandibular and maxillary canines and premolars for male and female patients in the sample of the present study. This is in agreement with the results of previous study on Saudis reported by Al-Khadra.\(^17\) Among other populations, several studies also reported either overestimation or underestimation of the width of unerupted canines and premolars when using the Tanaka-Johnston prediction equations.\(^1\)-\(^8\),\(^13\)-\(^22\)

The regression analysis in this study indicated that the sum of the mesiodistal width of the mandibular permanent incisors is a good predictor for those of unerupted canines and premolars. The correlation coefficient ranged from 0.51 to 0.61, which is considered slightly high and comparable to those reported for the Jordanian,\(^9\) the Iranian,\(^11\) and Thai population,\(^21\) and higher than those reported for the Nepalese.\(^12\) The coefficient of determination \( r^2 \), indicators of how well the predictively of the regression equations, ranged from 0.27 to 0.37 in this study. These were comparable to those reported for the Turkish,\(^13\) and white Brazilians.\(^21\) The standard error of estimate ranged from 0.96 to 1.11 and demonstrates the reliability of the prediction equations proposed in this study.

The results of the present study revealed that the Tanaka and Johnston equation is not applicable to Saudis. However, further work is needed on a large representative sample from different parts of the kingdom to represent the population of Saudi Arabia and to draw a firm conclusion.

In conclusion, the Tanaka and Johnston prediction equation overestimated the sum of mesiodistal widths of mandibular and maxillary canines and premolars for male and female patients in the sample of the present study. The following prediction equations were derived for Saudis: males (maxilla: \( Y=10.3+0.49X \), mandible: \( Y=9.7+0.49X \ )); and females (maxilla: \( Y=11.7+0.37X \), mandible: \( Y=11.3+0.39X \)).
